

For halobenzene:

-I effect of "X" > +R effect of "X" for rate of Electrophilic Substitution  
+R effect of X > -I effect of X for orientation of electrophile

Ex: ① Arrange following in decreasing order of rate of electrophilic substitution Rxn.

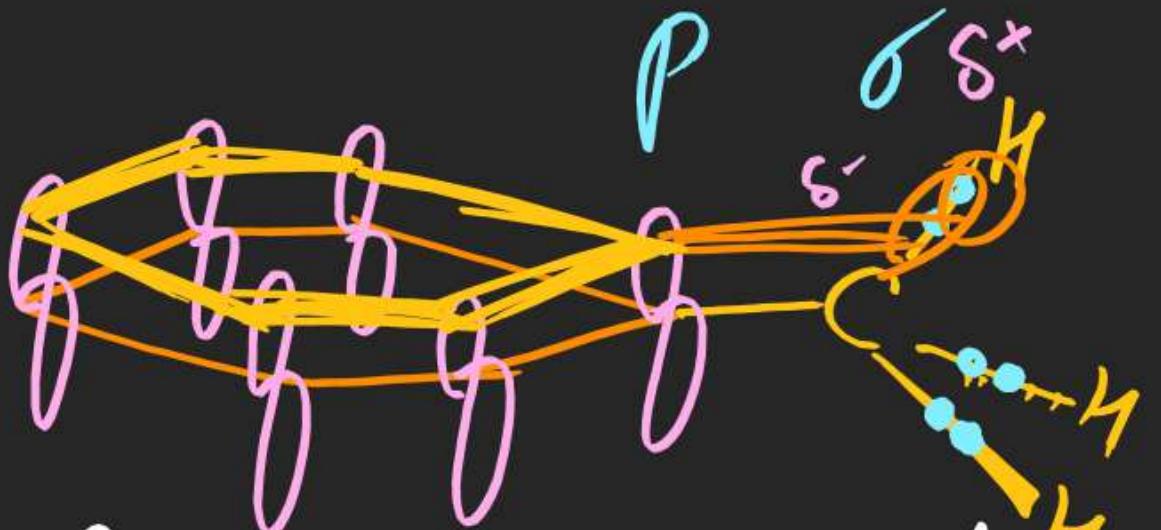

$\Rightarrow$  But experiment shows actual order  
of Rate of electrophilic attack is

सही है

$$A > B > C > D$$

(due to effect)

This order can be explained by overlapping b/w 'P' orbital of Benzene with  $\sigma$  orbital of C-H Bond of directly attached alky group.

(vi) H effect is weaker effect than R effect

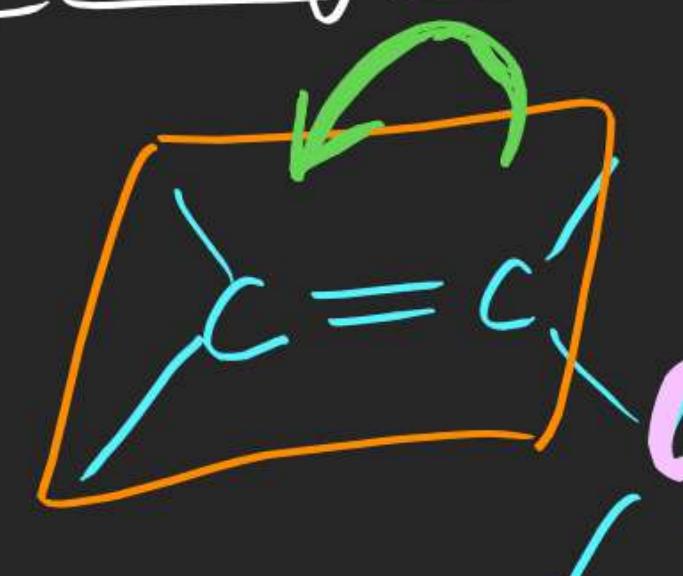

$$R > H > I$$

(vii) Permanent effect.

(viii) Distance independent effect

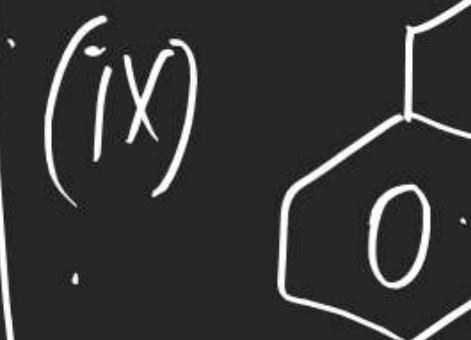

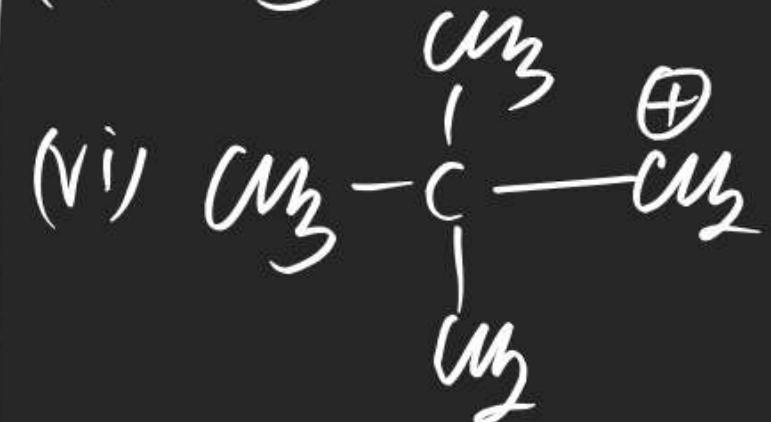

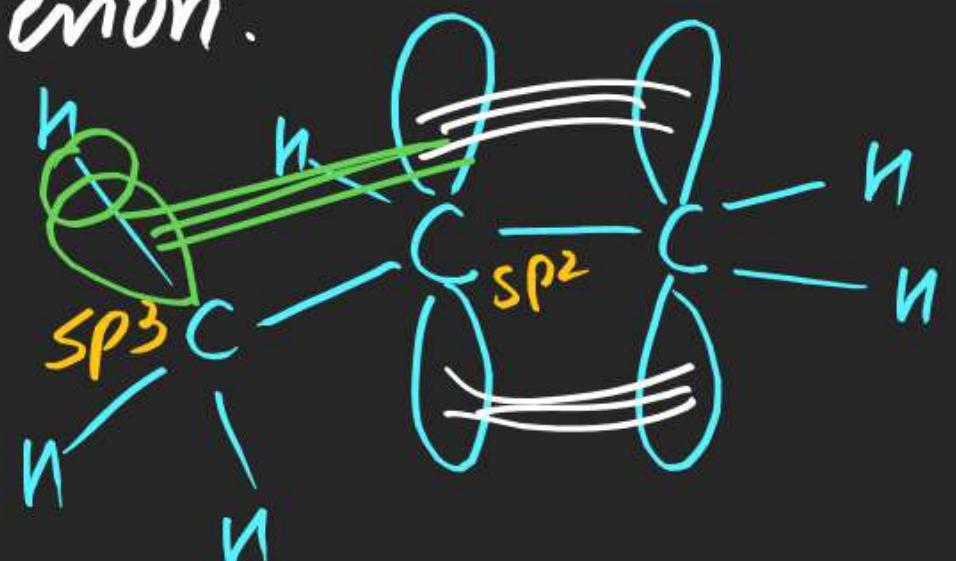

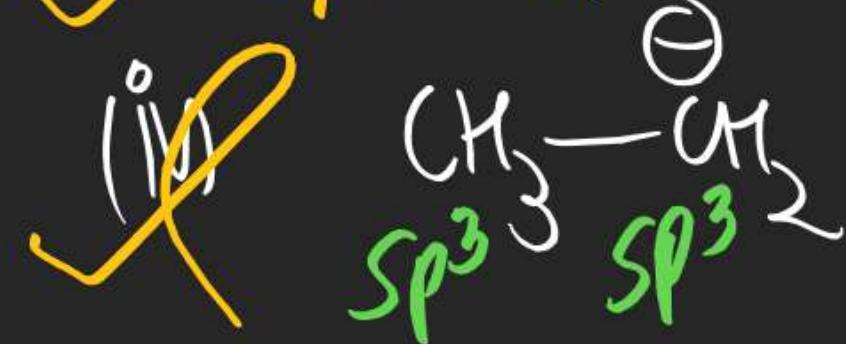

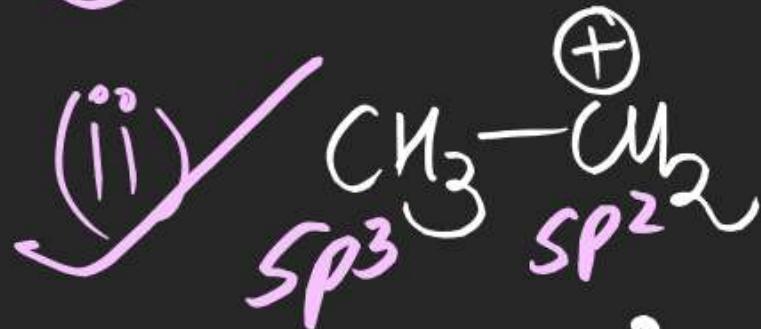

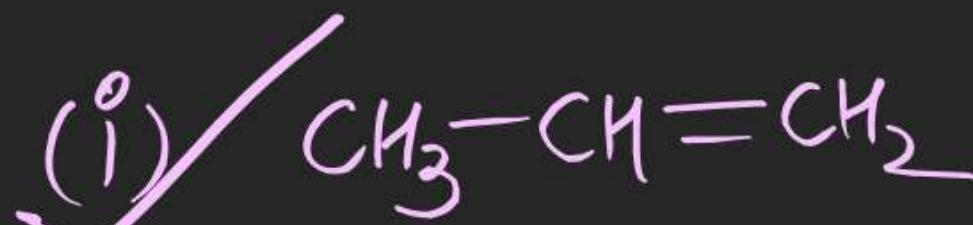

Types of H effect:

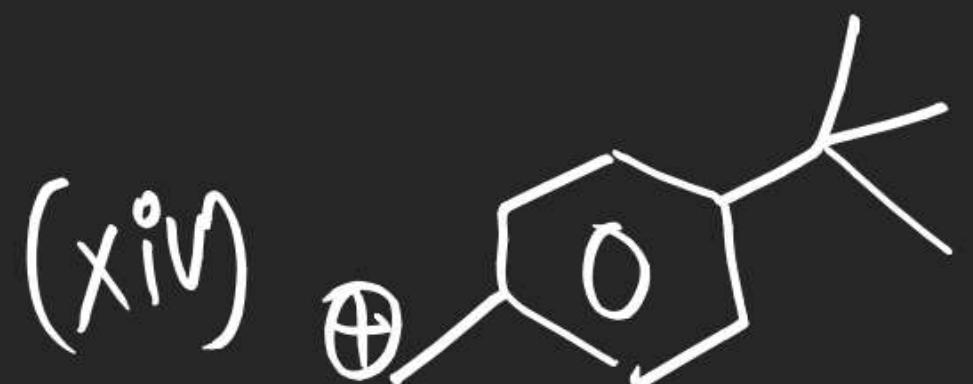

(1) + Hyper Conjugation effect (+H effect) Permanent displacement of  $\pi e^-$  density away to directly attached alkyl group due to its  $\sigma (C-H)$  bond  $e^-$ , is known as

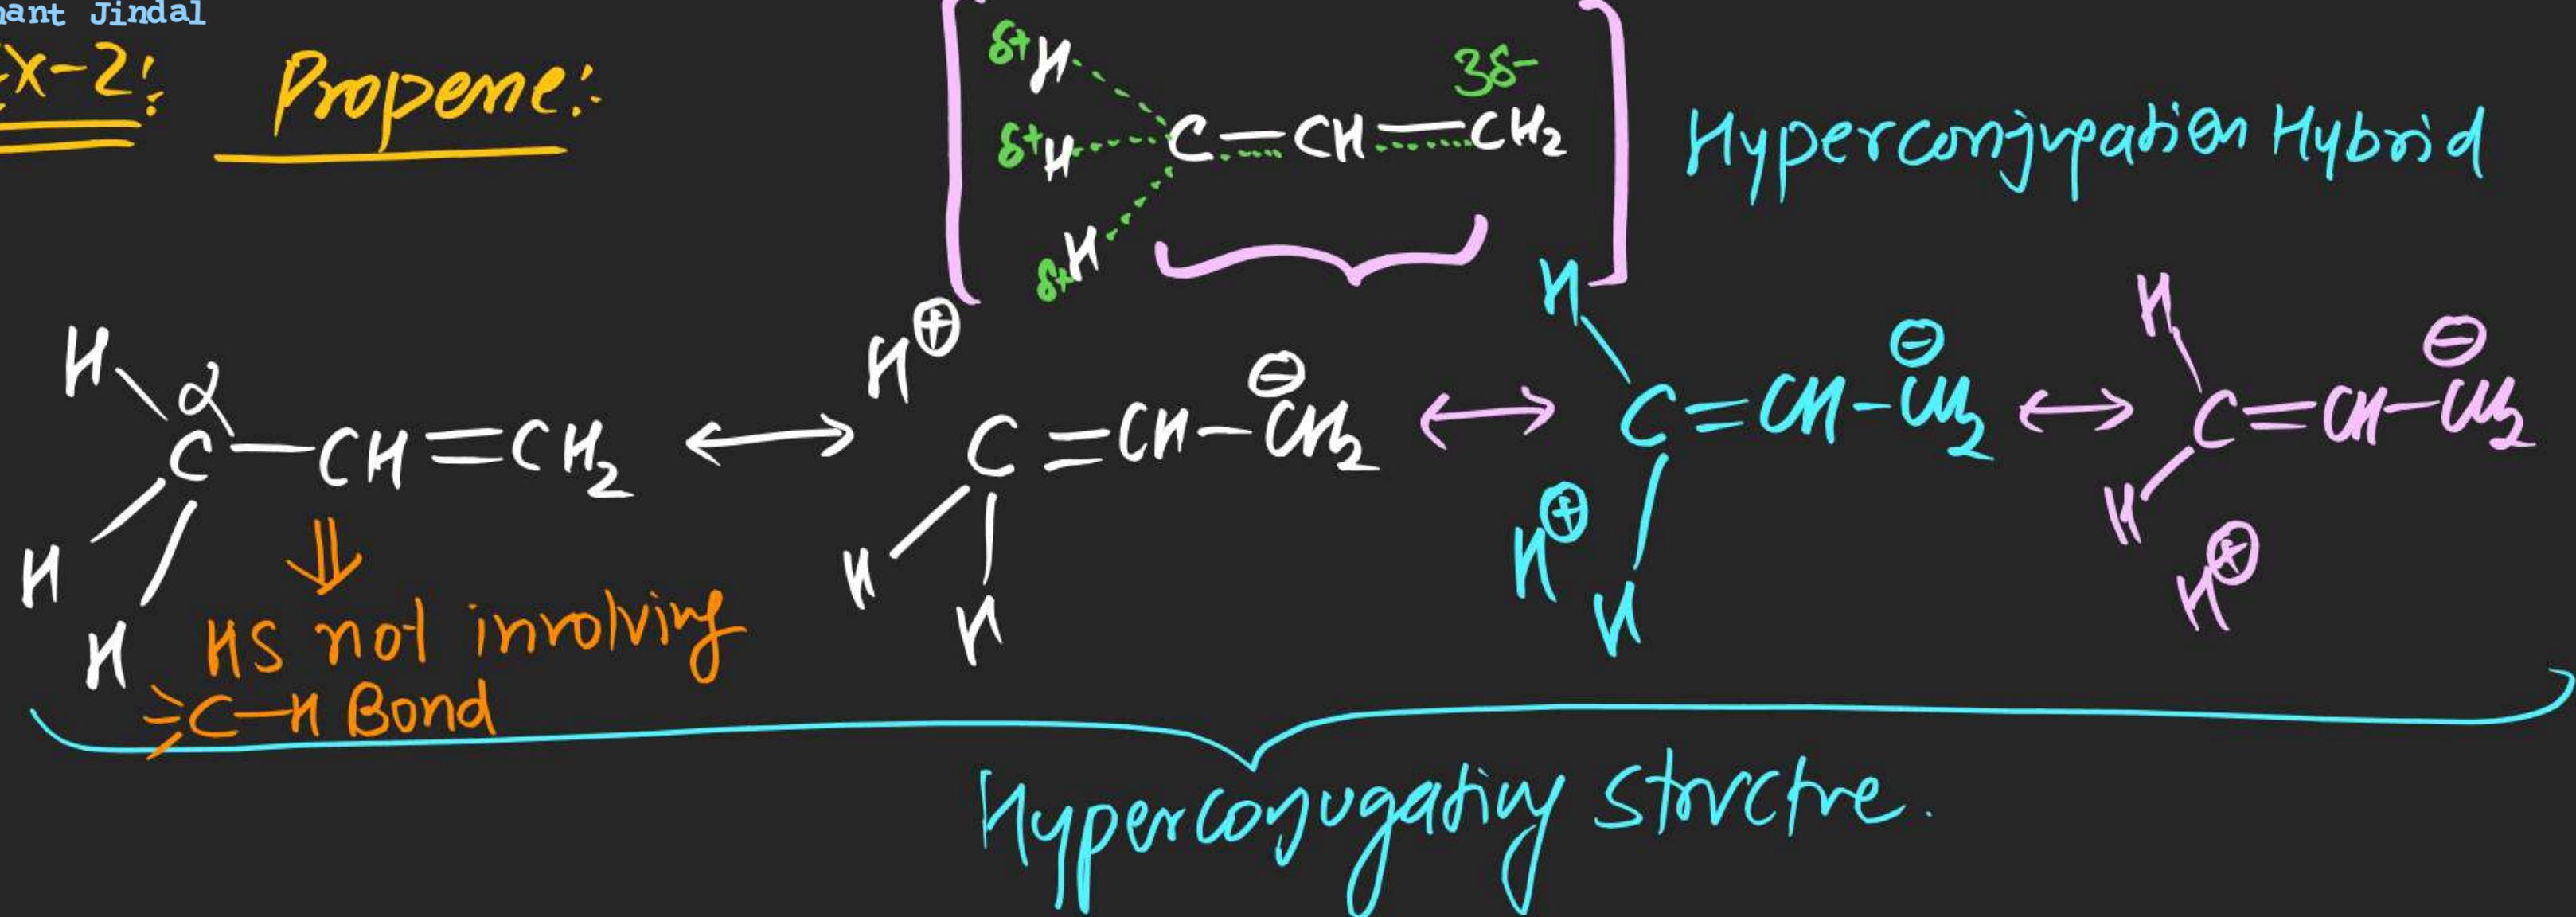

+H effect of that alkyl group.

Ex: (i) which of the following containing H effect phenomenon.

Ex-2: Propene:

Note: (i) The effect is EDONATING effect.

(ii) Total no. of HS = HS not involving C-H Bond + HS involving (-H Bond)

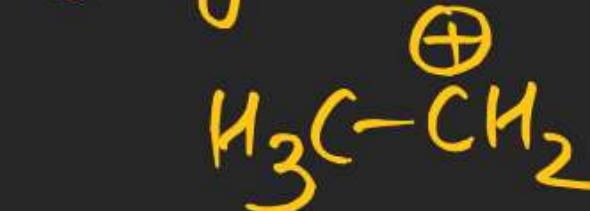

$$= 1 + N_{dH}$$

(iii) Total no. of HS involving (C-H) Bond = None

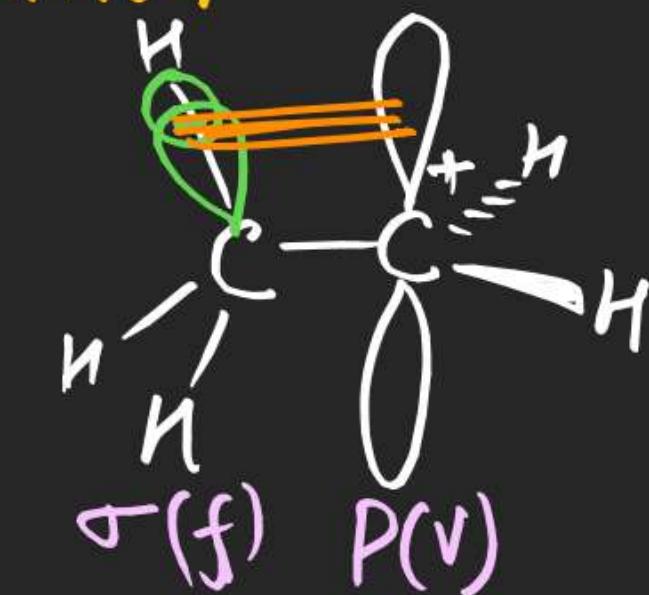

(iv) +H effect increases e<sup>-</sup> density at ortho & para position for electrophilic attack.

(v) Orbital overlapping in

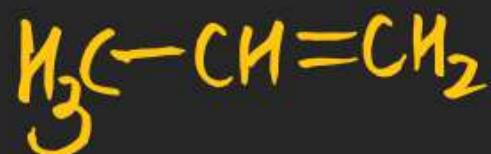

Ethyl Carbocation

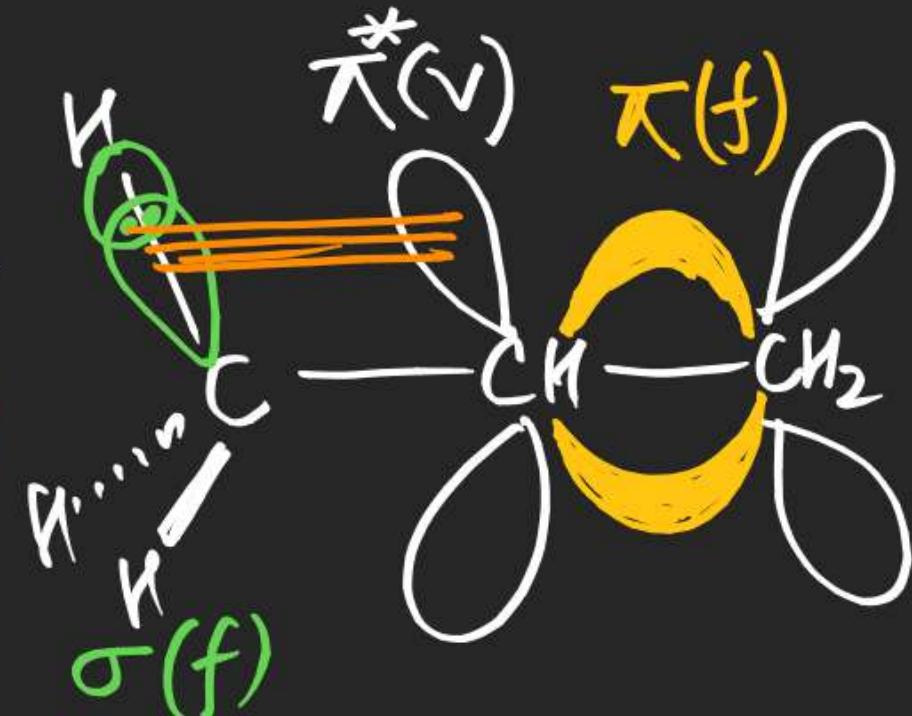

$\boxed{\sigma(f)-p(v)}$

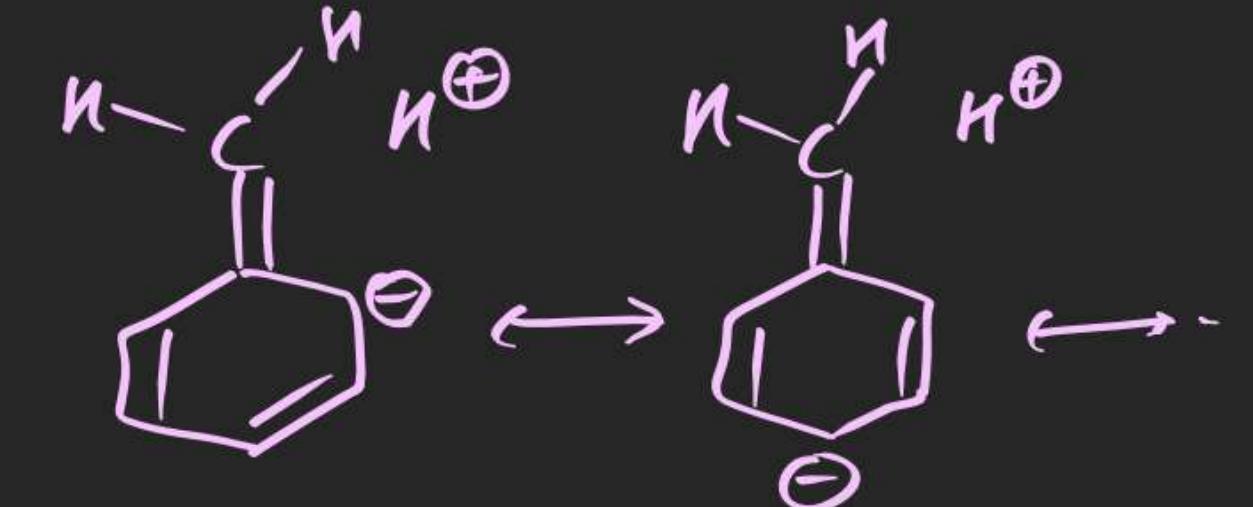

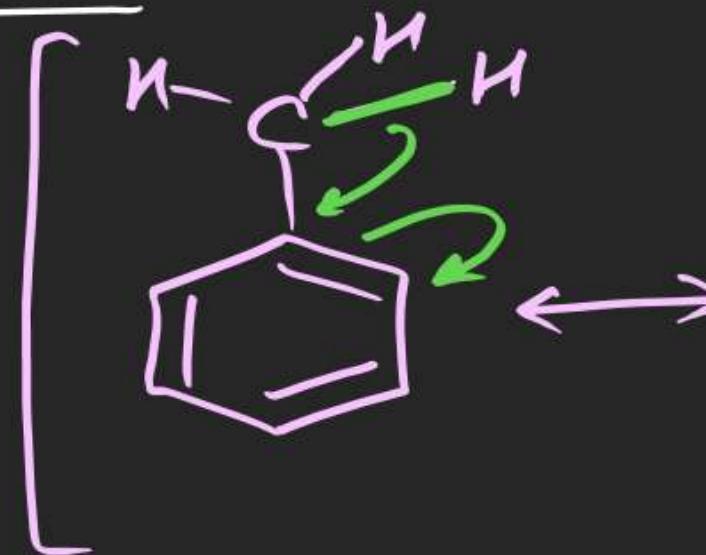

& in Propene

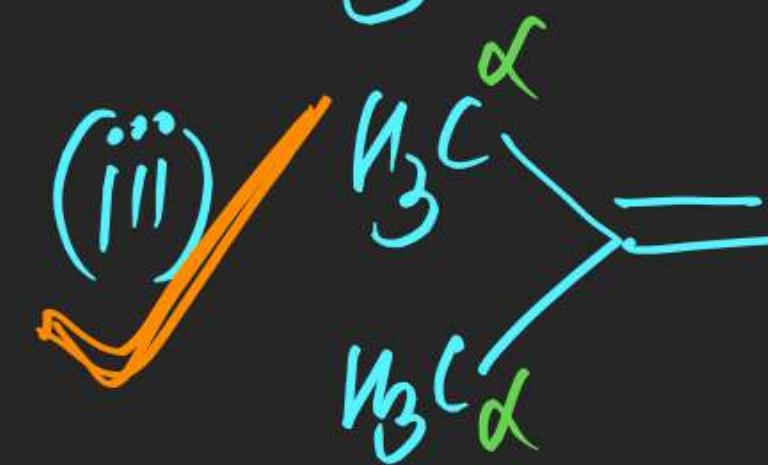

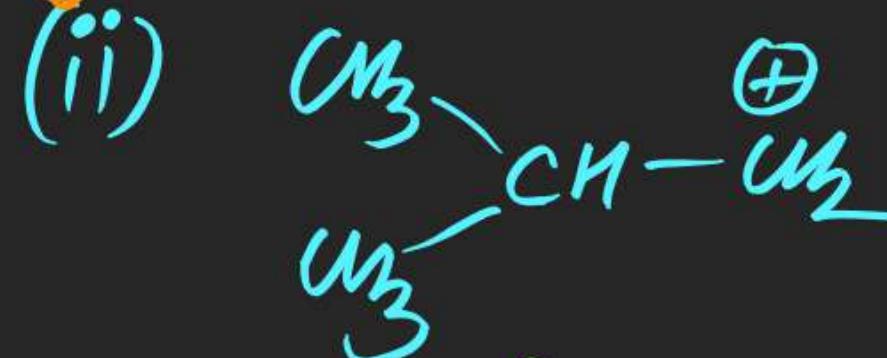

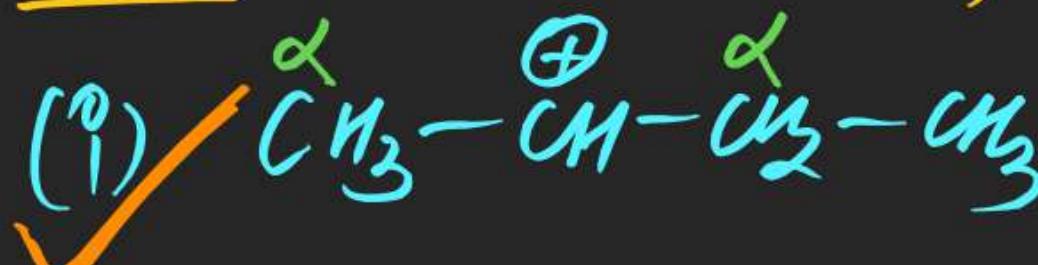

$\boxed{\sigma(f)-\pi^*(v)}$

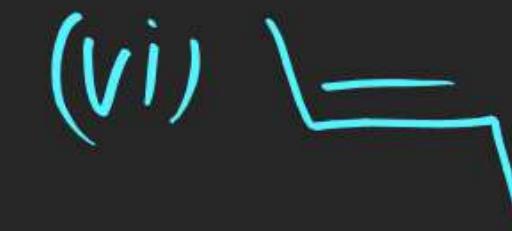

Ex-3:- Toluene

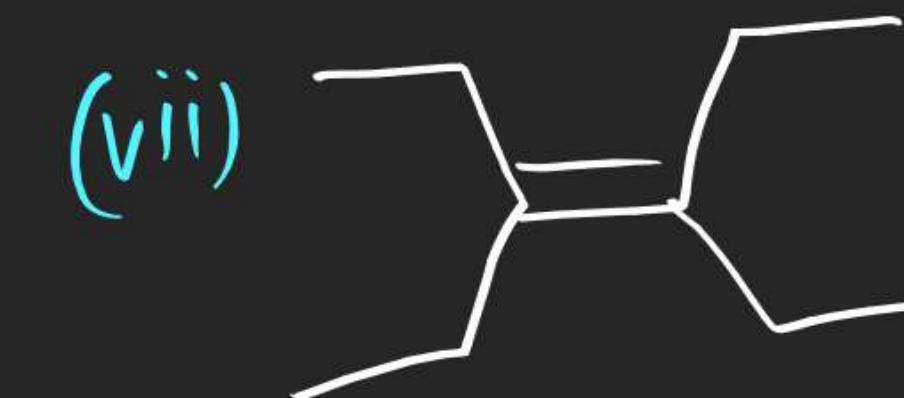

Ex-4: Total no. of HS strininvolving C-H Bond.

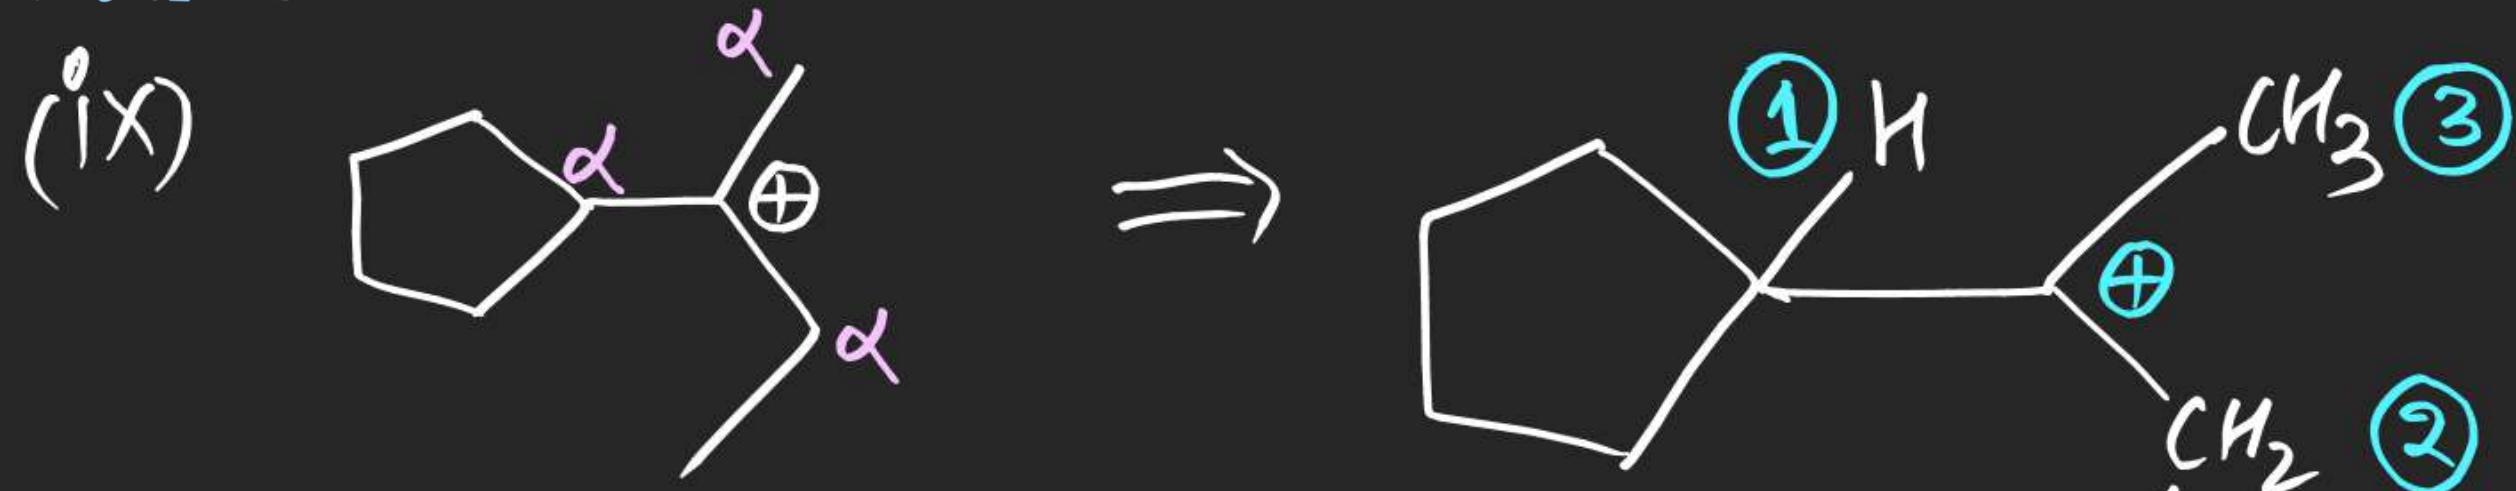

⑤

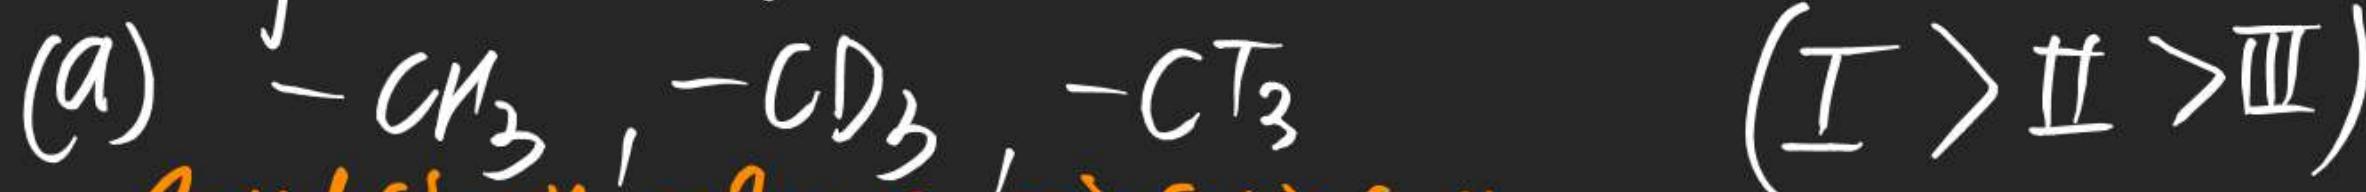

⑥

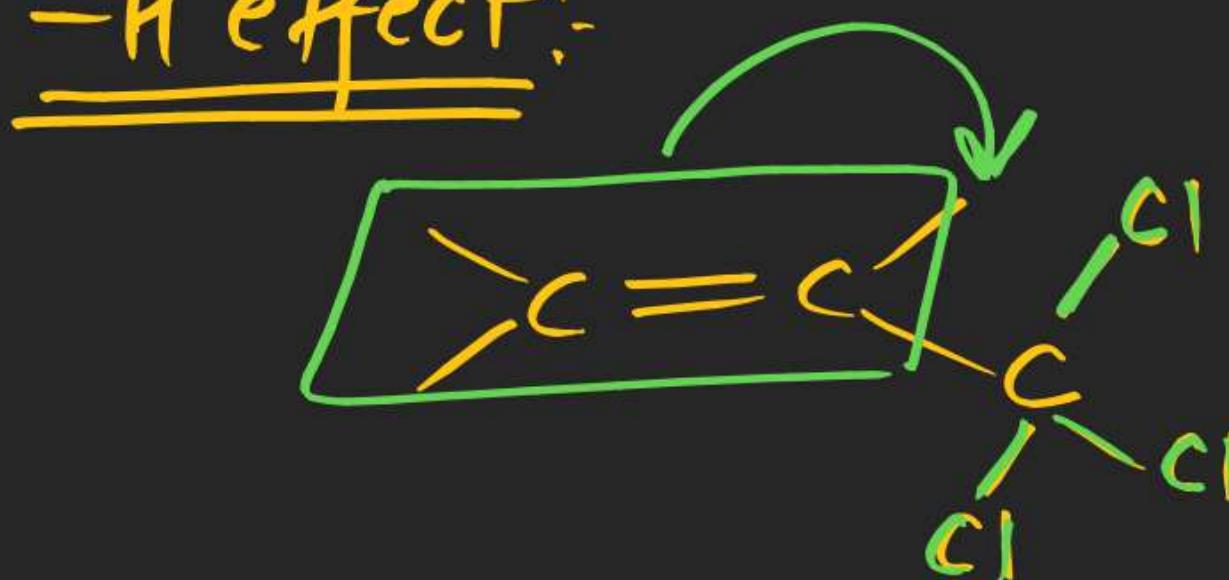

Note:  $\text{H}$  effect depends on Bond Strength  $\text{H}_3\text{C}$  following in  $\downarrow$  order of  $+\text{H}$  effect when attached with a  $^{sp^2}$  carbon

Bond Strength order  $\text{C}-\text{T} > \text{C-D} > \text{C-H}$

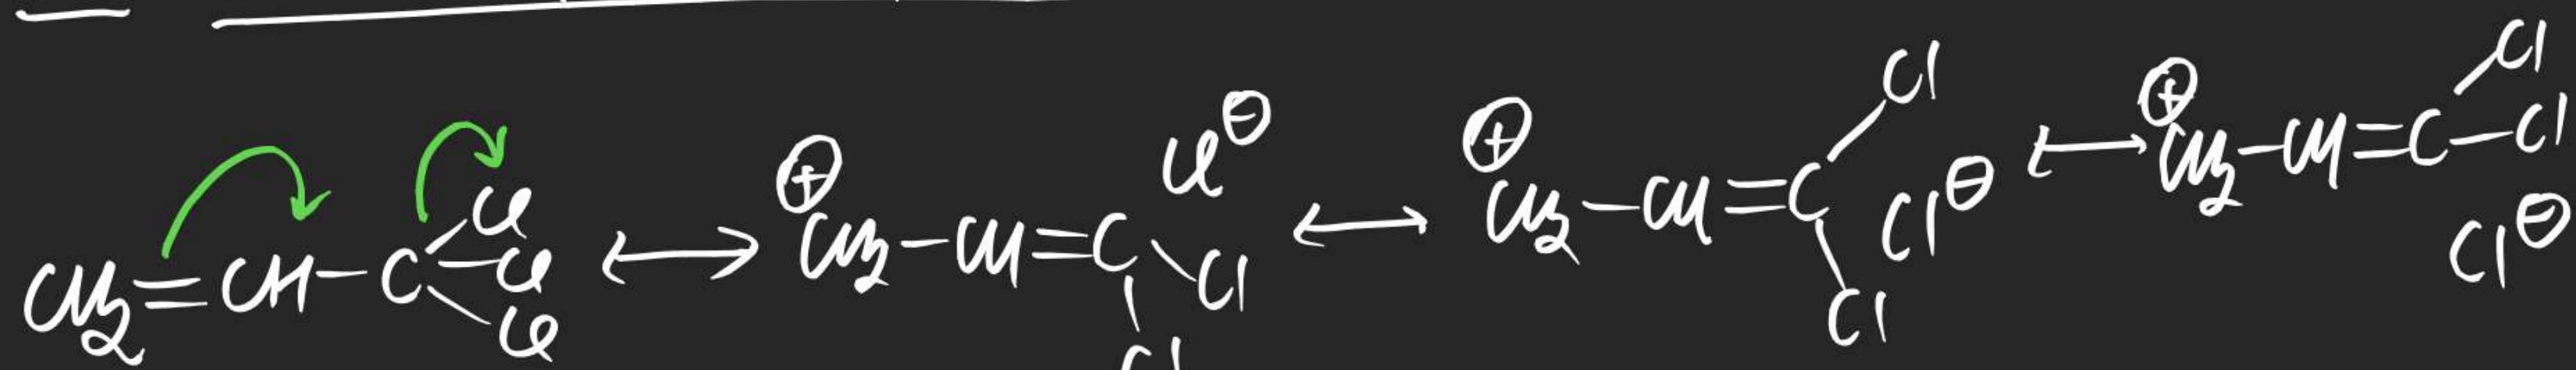

(#)  $\text{-H effect}$ :

when  $\pi e^-$  density gets displaced towards attached group ( $-\text{CCl}_3$ ) it is known as - H effect of  $-\text{CCl}_3$ .

Ex: 3,3,3-Tri Chloro Propene:

Note (i) -H effect is EW effect.

Resonance effect  $>$  Hyperconjugation effect  $>$  Inductive effect

ED effect

+R effect

+H effect

+I effect

EW effect

-R effect

-H effect

-I effect

### Stability of Reaction Intermediates :

(x) Stability of Carbocation  $\propto$  ED groups (+R, +H, +I)  $\propto \frac{1}{-I, -H, -R}$

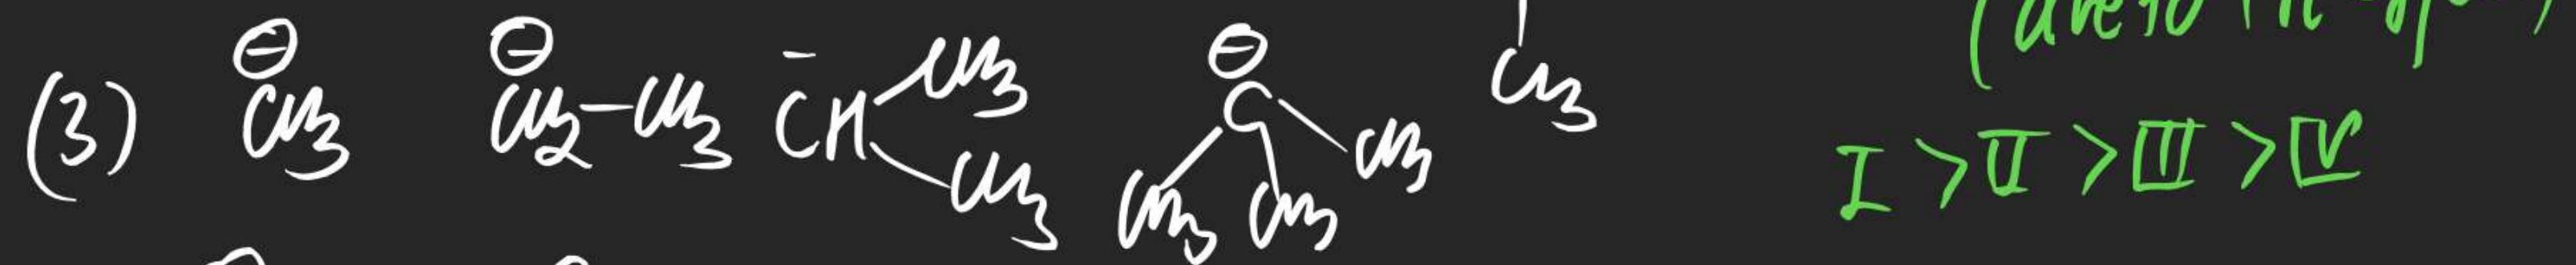

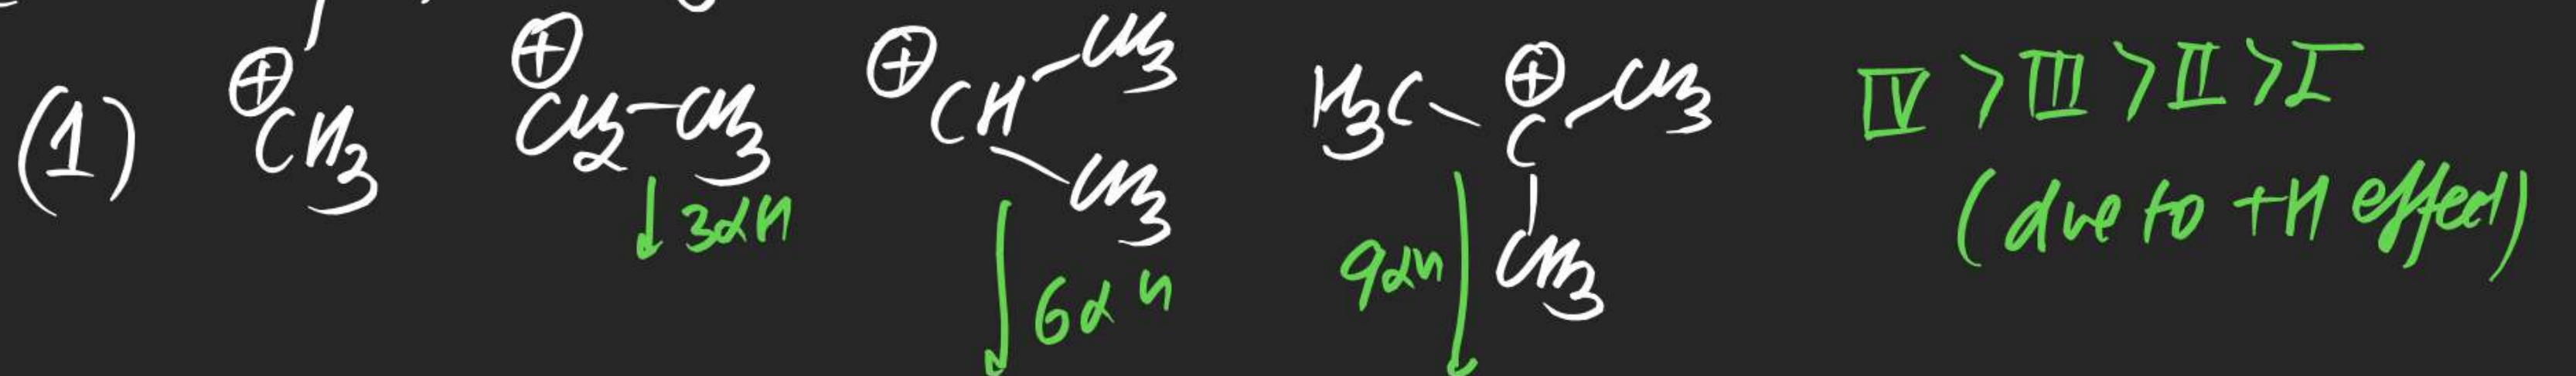

(x) Stability of Carbon free Radical  $\propto$  ED groups (+R, +H, +I)  $\propto \frac{1}{-I, -H, -R}$   
 $\propto$  EW group (-R)

(x) Stability of Carbanion  $\propto$  EW groups (-R, -H, -I)  $\propto \frac{1}{+I, +H, +R}$
